
The IEEE working group charged with representing the interests of the United States to WG13 of SC22 of JTC1 of the ISO/IEC requests that the United States register its vote against the publication of DP10514 (SC22/N738, referred to here as D106) as a Draft International Standard for the following reasons:

0. We believe that the US community would not accept the current Draft Proposal (DP) because it neither codifies established practice, nor gives adequate justification for its differences therefrom. In 1987 the U.S. committee drafted this statement.

The general philosophy of the committee and what the committee felt to be the charter for Modula-2 standardization:

1) Clarify imprecisions and contradictions in the language as we know it.
2) Avoid removing language features unless necessary.
3) Avoid changing language features without good reason.
4) Avoid semantic changes that are not associated with syntactic changes.
5) Minimize language extensions.
6) 'Deprecate' obsolete features rather than removing them (i.e., have compilers accept these features while issuing warning messages, and warn users that such features may not be supported in the long term).
7) Flag dangerous programming practices, often by importing from SYSTEM.

We are disappointed that WG13 has been unable to state its goals or philosophy.

1. The document is incomplete, as many open 'to-do' items, small errors, etc. We are extremely concerned that there has been no formal (e.g., automated) verification of the VDM.

2. Although the definition of Modula-2 should be fully and separately supported both by VDM and by English text, we find that in the D106 neither method adequately defines the language. D106 uses English text too sparingly and the text is often incomplete and inadequate. The dialect of VDM used in D106 is still undefined, leaving the DP in the
illogial position of providing an undefined definition of Modula-2. We cannot support the definition given by the D106 since we cannot know what the definition means. A reference to an out-of-print book [Jones80] is not a legitimate substitute for a definition, especially as that book does not describe the dialect of the VDM used in D106; neither is there a reference to Cover a moving target such as the new VDM-SL NW1. We agree that having the VDM is a good idea, provided the formalism has a complete, stable, and publicly available definition, either included in the DP or referenced by it. If not so defined, the formalism must be removed.

3. Alternative tokens Sec.5.5. We still hold our position of August 1988 that the alternative symbols for square brackets ("[", "]") create unnecessary syntactic ambiguity to no positive gain. We reiterate our proposal that "(!" and "+") be used instead.

4. Requirements clauses Sec.4.11. The various minima suggested in Sec.4.11 are unnecessary, technically problematic, and have the potential of delaying the standards process if adopted. We propose that all suggested minima be eliminated except for the single requirement that SET be large enough to cover CHAR.

5. Value constructors Sec.6.7.5. There is general consensus against array and record non-constant value constructors. They add no new functionality at significant cost both to the definition and to compiler complexity. Many would be willing to undo Wirth's dynamic set value constructors, if that were necessary to get rid of array and record value constructors.

6. Comment bodies Sec.5.8.1. We believe the intent of the language comment facility is

a. Comments shall not change the meaning of the program, and
b. As far as possible, one should be able to convert any piece of legal program text into comment by enclosing it in "(" ...)" brackets, regardless of the presence in that text of comments, compiler directives, strings, or other constructs.

It is important that the DP clearly state this intent, even if it cannot properly be captured in a syntax specification, and that the implementor be encouraged to honor this intent.

7. Compiler Directives Sec.5.8.2. We note several problems with compiler directives:
   a. A "S" is a national currency symbol, and is not therefore appropriate as the default directive symbol.
   b. Arbitrary white space before the "S" unnecessarily complicates scanning the directive.
   c. The nesting interaction between directives and normal comments is likely to cause problems.

We reiterate our suggestion of 1988 that "<" and "/> be used as bracketing symbols. It should also be stated that compiler directives can be commented out.

8. Machine Addresses in Variable Declarations Sec.6.2.5. We request that MACHINEADDRESS be a record type in accordance with the proposal presented at Linz by Keith Hopper of New Zealand. In D106, MACHINEADDRESS is a function; since function calls cannot appear in constant expressions, this precludes the intended use of MACHINEADDRESS as a way to specify the address of a variable.

9. Constant Expressions Sec.6.7.7. This section requires constant real expressions to yield the same result whether computed at compile time or at run time. Although we note that a significant subset of the potential users of Modula-2 insist on this property, it causes a severe problem on machines where real arithmetic is dynamically changeable. For example, on a machine with IEEE-754 floating point, the declaration,

\[
\text{CONST halfpi} = \text{PI} / 2.0;
\]

will compute a value dependent on the current rounding mode of the floating-point operations. Since this mode can be changed during program execution, the computed value cannot in general be decided at compile time. While this example could in principle be dealt with by deferring evaluation of the constant until execution time, the problem is insuperable in cases such as

\[
\text{TYPE A = ARRAY[1..\text{TRUNC(exp)}] OF INTEGER;}
\]

where the value is required at compile time but cannot then be computed. This problem should be addressed and resolved.

10. Exceptions Sec.6.12, Sec.7.3, Sec.8.2, Annex G. D106 does not include a single complete model for adding an exception-handling capability to Modula-2. Since most of the proposed libraries presuppose that such a capability is defined, the failure to reach closure on this issue has an impact on both the definition and the standardization process. The evaluation criteria offered in N328 Sec.3 appear sound to us, and in the light of these criteria we observe

a. Any proposal meeting these criteria is likely to involve a language change too great to be admissible at this stage in the standardization process, and
b. Any proposal not involving a language change is unlikely to offer sufficient benefit to justify its inclusion.

Accordingly, we propose that all references to exception modules be removed from the DP. If WG13 believes that one final attempt should be made to revise this facility, then we suggest that a very simple and primitive setjmp/longjmp model, such as D70/N247 proposal 2, if not overly embellished, may provide an approach that can yield an acceptable minimal proposal in the time available.
11. CAST <> bitsize Sec.7.1.3.4. The definition of CAST should be changed so that:

a. The effect of CAST on values of ambiguous sizes (i.e. the abstract types Z, R) is implementation-dependent,

b. The CAST of a typed value into a type of different size is implementation-dependent, and

c. A CAST of a value designator whose alignment is "incorrect" for the target type is implementation-dependent.

12. Lexis of Identifiers Sec.5.3. If low-line ("_") is to be permitted as a component of an identifier, then it should be permitted wherever a letter is permitted. The lexis should not be made more complicated merely to enforce one body's view of good taste.

13. Termination Sec.7.1.2. We reiterate the US position of 1989 as described in P115, dated 4 August 89. Termination as drafted is unnecessarily complex, provides little additional benefit over P115, and has undesirable interactions with exception handling and coroutines.

14. Forward reference pointer types. The problem exhibited by the following apparently legal code fragment should be resolved:

```plaintext
TYPE T=O;
PROCEDURE a;
VAR v: 'T;
PROCEDURE b;
BEGIN
  v:=x; (* what code generated by one pass
        compiler? *)
END b;
TYPE T=T-R;
END a;
```

15. SYSTEM module Sec.7.1. In abstracting a storage model underlying SYSTEM, the D106 lets the abstract model pervade the definition module. Thus what should have been simple access to machine primitives has become complex operations on pieces of storage that are rarely directly supported by the native hardware. The DP should not require module SYSTEM to export constant and type identifiers other than the following:

```plaintext
CONST
  LOCSPERWORD = (* implementation defined *);
  BITSPERLOC = (* implementation defined *);
  BITSPERWORD = BITSPERLOC*LOCSPERWORD;
  TYPE
  LOC; (* an opaque type equivalent to SET OF [0..BITSPERLOC-1]*)
  WORD; (* an opaque type equivalent to SET OF [0..BITSPERWORD-1]*)
  BITSET = SET OF [0..BITSPERWORD-1];
  ADDRESS = POINTER TO LOC;
  MACHINEADDRESS = RECORD
    (* implementation defined *)
  END; (* required by KN proposal *)
```

16. String constant concatenation Sec.5.5.2.5. A different symbol is needed for string literal concatenation, as "||" causes an ambiguity with case list separators; we suggest overloading the binary operator "+". There is also a problem with using the null string to denote the string termination character. The expression "a"+"b" should be the same as "ab" and not insert a string terminator in the middle.

17. Type transfer Annex E, p.16 (see CAST Sec.7.1.3.4). We were unable to find in D106 the type transfer of PIM (Programming in Modula-2 by Wirth). WG13 agreed to retain this feature but deprecate it. We suggest that, similar to NEW and DISPOSE, the old form of type transfer might require that SYSTEM.CAST be visible.

18. INTEGER and CARDINAL Sec.6.9.1. We were unable to find in D106 the relationship between the ranges of INTEGER and CARDINAL and the bounding constants known as K1, K2, and K3.

19. WG13 agreed that all changes from PIM would be noted in the document, and we observe that many are. We require that all changes from and clarifications to PIM be noted. We also request that in each future draft, all additions, changes, and deletions from the previous draft be marked with change bars or other appropriate mechanism, to facilitate proper and efficient evaluation of the draft proposals.

20. Coroutines Sec.7.2. While we can support moving coroutines to a separate module, we cannot support the syntactic and semantic changes made from PIM as they add no functionality and break existing code.

21. I/O Library Sec.9.2. Noting the lack of goals or rationale, as well as the size, complexity, and novelty of the proposed I/O library, we cannot support the proposal in D106. WG13 requested a small and simple I/O library be produced. We reiterate that request. We note that D75 of August 1988, which tried to address that request, has not been allowed to mature.
22. Strings Module Sec.9.4. The Strings module uses the look-ahead philosophy that WG13 purged from the I/O library after much debate. The current module is a radical departure from all previous implementations, complicating code, and is of no clear benefit to the programmer.

23. Module protection Sec.6.1.11; Procedure protection Annex G. Module protection, priority, and associated syntax and semantics should be removed from the Draft Proposal because:
   a. They are an extension to the language defined in PIM,
   b. They assume a non-universal machine model,
   c. They assume particular process and synchronization models, and
   d. They will cause serious problems when multi-processor Modula-2 is designed.

24. LowReal and LowLong Sec.8.3.1, Sec.8.3.2. The modules LowReal and LowLong currently specify a set of constants that define various parameters of the floating-point implementation. These values become invalid if SetMode() is ever called. A much more usable definition would be:

25. Concurrent Programming Modules Sec.9.3. The D106 has significant flaws:
   a. It mixes event handling with basic process operations.
   b. Important operations on process queues are not in this module, namely, Lock, EnterQueue, SuspendMe, and a way to release a lock.
   c. In the Semaphores module the definition is for general semaphores, not counting semaphores (the two are distinct), and the operator set is incomplete (e.g. no indivisible VP()).

---

**Summary of Balloting on the Modula-2 Draft Proposal**

The summary of the ballot is as follows:

Members supporting the proposal without comments: 4
Belgium, Finland, Hungary, Italy

Members supporting the proposal with comments: 3
Canada, Denmark, Japan

Members not supporting the proposal: 5
France, Germany FR, Netherlands, UK, USA

Members not voting: 8
Of these, China and Switzerland have had participation
and so has New Zealand (and we know they tried to vote!)

*The fifth meeting of SC22/WG13 is to be held from Monday June 4th to Friday June 9th 1990 in Milton Keynes, UK. The main business of the meeting is to review and process comments received on the Modula-2 draft proposal, to produce a response in the form of a disposition of comments paper, and to reach decisions on outstanding issues affecting the production of the next draft of the Standard.*
Discussion of a Standard Modula-2 String Module

An extract from the formal response to ISO on the Draft Proposal for Modula-2 criticizes the D106 draft as follows:

22. Strings Module Sec.9.4. The Strings module uses the look-ahead philosophy that WG15 purged from the I/O library after much debate. The current module is a radical departure from all previous implementations, complicates code, and is of no clear benefit to the programmer.

The purpose of this note is to amplify on that extract.

We note that there seems to be remarkable consensus among existing libraries as to what should be in a Strings module, and what the parameters to various routines should be.

In keeping with our belief that the Standard should reflect existing practice wherever possible, the US requests that the standard specify a Strings module that can be summarized most simply as follows, noting that the semantics of these routines are essentially as in the corresponding places in D106.

Notes:

After examining about 18 libraries or library proposals we make the following observations:

PROCEDURE Length -

There is unanimity among vendors about this one. D106 introduces the pervasive LENGTH in its place.

PROCEDURE Compare -

10 vendors use INTEGER, 4 use an enumeration type as the result type. We regard the adoption by D106 of the enumeration as preferable.

PROCEDURE Extract -

Many vendors call this "Copy" or "SubStr". The D106 name seems a good compromise, noting the misleading interpretation that could be placed on "Copy".

PROCEDURE Insert -

Nearly all libraries examined had parameters in this order. D106 was in a minority of 1 in deviating (presumably in an attempt to "tidy up").

PROCEDURE Concat -

D106 does not have this one at all. 14 of the libraries examined had it, and 12 have the parameters in this order. It seems very popular. Those few who do not have Concat have Append, and justify this by saying that most Concat operations are really Append. However Append is an easy call of Concat, and the reverse is not true. Furthermore, of the 6 libraries examined that supplied Append, most had the parameters in the opposite order to those given in D106. Finally we note that

DEFINITION MODULE Strings;

PROCEDURE Length (StringValue : ARRAY OF CHAR) : CARDINAL;
(* returns the length of StringValue *)

PROCEDURE Assign (Source : ARRAY OF CHAR; VAR Destination : ARRAY OF CHAR);
(* copies Source to Destination *)

PROCEDURE Extract (Source : ARRAY OF CHAR;
   StartIndex, NumberOfExtract : CARDINAL;
   VAR Destination : ARRAY OF CHAR);
(* copy NumberOfExtract characters from Source to
   Destination, starting at StartIndex in Source *)

PROCEDURE Delete (VAR StringValue : ARRAY OF CHAR;
   StartIndex, NumberOfDelete : CARDINAL);
(* delete NumberOfDelete chars from StringValue,
   starting at position StartIndex *)

PROCEDURE Insert (Source : ARRAY OF CHAR; VAR Destination : ARRAY OF CHAR;
   StartIndex : CARDINAL);
(* insert Source into Destination at position StartIndex *)

PROCEDURE Concat (StringValue1, StringValue2 : ARRAY OF CHAR;
   VAR Destination : ARRAY OF CHAR);
(* concatenate StringValue2 to StringValue1 and place the resulting string
   in Destination *)

TYPE
   CompareResult = (less, equal, greater);

PROCEDURE Compare (StringValue1,StringValue2 : ARRAY OF CHAR) : CompareResult;
(* Return: less, equal, greater according as StringValue1 < => StringValue2 *)

PROCEDURE FindNext (Pattern, StringValue : ARRAY OF CHAR;
   StartIndex : CARDINAL; VAR PatternFound : BOOLEAN;
   VAR PosOfPattern : CARDINAL);
(* look for next occurrence of Pattern in StringValue, starting search from
   StartIndex. PosOfPattern returns start position of Pattern if PatternFound *)

END Strings.
the absence of Concat has nothing to do with the proposed concatenation operator for string literals.

**PROCEDURE FindNext**

The popular alternative is something like

**PROCEDURE Pos (Pattern,**
**  StringValue : ARRAY OF CHAR) :**
**  CARDINAL;**

(* Returns index of first occurrence of Pattern in**
**  StringValue or > HIGH(StringValue) if no match is**
**  found *)

Use of this is, admittedly, awkward. 9 vendors have it like this. 4 more discerning ones have

**PROCEDURE Pos (Pattern, StringValue : ARRAY OF CHAR;**
**  StartIndex : CARDINAL) : CARDINAL;**

and the other three have other ways of returning the "result". The idea that 0 ... Length(StringValue)-1 implies Success and
>HIGH(S) (or variations on this theme) implies failure is awkward. The D106 idea has clear merit. Traditional Pos is easily written in terms of FindNext, but the reverse is not true.

**Summary**

- We request the substitution of Concat for Append.

- We request the retention of Length, and that consideration be given to the deletion of the pervasive LENGTH.

- Insert should have parameters to confirm to existing practice.

- FindPos is an improvement over the "popular" Pos, and could be retained as the old Pos is easily defined in terms of it.

- We request the deletion of the following. If W13 is keen to standardize them we ask that they be placed in a subsidiary library.

  String1
  BigStringCapacity
  BigString
  CanAssignAll
  CanExtractAll
  CanDeleteAll
  CanInsertAll
  CanReplaceAll
  Replace
  CanAppendAll
  Append
  Capitalize
  FindPrev
  FindDiff

**Error detection**

We note that there are 5 approaches that could be taken to run time error handling in a strings library

(a) Ignore them - the D106 procedures never fail to return some sort of result (though it may not be what one intuitively wishes). This seems to be the common practice, and is in line with the proposal above.

(b) Provide pre-event predicates (as in D106) so that conscientious programmers could test, and the more daring or traditional could follow prevailing practice at their peril. Academically this has some merit over all the others, but we doubt that it is necessary to specify it in full detail, as the predicate functions are easy to write, even if the various Insert, Concat, Find, etc. ones are tricky because of the awkward Modula string representation.

(c) Provide the module with "state", and a post event predicate

**PROCEDURE LastStringResult () : SomeEnumerationType;**

to allow conscientious programmers to pick up the mess later. We have never seen this anywhere, but the analogies with various libraries that take this approach to I/O are obvious.

(d) Provide each routine with an extra VAR OK : BOOLEAN parameter to force the programmer to be aware of error possibilities, even if he does not bother to check them. This approach was advocated by the Ad-Hoc Library in 1984, but we have not seen it put into many current libraries.

Note that "post testing" for string using either of (c) or (d) is "safe", as even in the cases of failure one gets some result, and does not crash the system (as one might do when dividing by zero etc).

(e) Raise an exception. This does not appear to be common practice (with present implementations "raise exception" would almost always mean "run time error and halt").
Some Ideas about Pascal Programming Nomenclature
David Craig
736 Edgewater, Wichita, Kansas 67230
March 1990

In my 10 years programming with Pascal for various machines I’ve developed a simple set of nomenclature guidelines for Pascal programs. The nomenclature guidelines are as follows:

Pascal reserved words;
- All reserved words are in uppercase characters
  Example: PROGRAM, UNIT, BEGIN, END, CONST, TYPE, VAR, ARRAY

Program procedure and function names;
- Application routine names start with a lowercase character, contain underscores between routine name words, and the routine name words start with uppercase characters.
  Example: find_Expression_Token,
           list_DataBase_File_Reader
- System or built-in library routine names start with an uppercase character.
  Example: GetNextEvent, ZoomWindow
- All local routine constants, types, and variables are in lowercase.
  Example: time_of_day, list_index, user_is_done
- All local routine constant names start with the prefix 'k_'
  Example: k_size_of_list
- All local routine type names start with the prefix 't_'
  Example: t_paoc, t_current_window_ptr
- Underscore characters should be used as much as possible in all names since this character improves the readability tremendously.
  Example: use time_of_day instead of timeofday

Program globals;
- Global constants start with the prefix 'gc_' (Global Constant)
- Global types start with the prefix 'gt_' (Global Type)
- Global variables start with the prefix 'gv_' (Global Variable)
  Example: gc_List_Size, gt_PAOC, gv_ApplicationParms
- Global types and global variables based upon those types should have similar names
  Example: If the type is named gt_MyType, then the variable should be named gv_MyType

Unit interface routines;
- Unit routine names start with a two character prefix that corresponds to the unit name
  Example: EP_Tokenize_Expression for a routine in a unit named Expression_Parser
- Unit global constants start with the unit name prefix and 'c_'
- Unit global types start with the unit name prefix and 't_'
- Unit global variables start with the unit name prefix and 'v_'
  Example: EP_c_Max_Token_Length, EP_t_Token_List,
           EP_v_Token_Offset

Unit implementation globals;
- Global constants start with the prefix 'pc_' (Private Constant)
- Global types start with the prefix 'pt_' (Private Type)
- Global variables start with the prefix 'pv_' (Private Variable)
  Example: pc_Max_Name_Length, pt_Dynamic_Lis,
           pv_Unit_Init_Slate

These nomenclature ideas have proved their worth in many of my Pascal programs. For small programs, they may not be too useful, but for large programs (5,000+ lines) that require several months to write these guidelines are to me almost indispensable. Other programmers may consider these ideas a waste of time. But the small waste of time it takes to use these ideas, in my opinion, will be far less than the waste of time at a future date when a programmer is trying to understand either his or another person’s program which does not follow these guidelines.

These ideas may be difficult to implement with compilers that handle only short names. For example, my Lisa Pascal compiler only uses the first 8 characters of names while my Macintosh MPW Pascal compiler uses the first 63 characters.

These ideas are based loosely upon the “Hungarian” style that MicroSoft uses for its C projects. Any comments, positive or negative, about these ideas are welcome. The ultimate goal of these ideas is to make programming easier to understand and maintain.
PMPData is a data entry/validation library module for Modula-2 written in TopSpeed Modula-2, version 1.17.

The main procedure in PMPData is UserInput. The code in UserInput allows you to make one procedure call to perform data entry & editing of most data types (standard plus string), in addition to calling client-module defined validation procedures.

The ability to provide entry and editing on most data types is handled through the use of generics.

Data is passed to and from UserInput in the form of a stream (array) of bytes. This allows any data type to be passed to UserInput, even though UserInput only handles standard data types and strings.

Data validation is provided by passing the address of the input data to the validation procedure. This allows UserInput to pass one address to one validation procedure since a variable of type address can store any data type.

Types used in the library:

```
dataType = (boolean, cardinal, char, integer, real, longcard, longint, longreal, stringArray);
```

Types of dataType define what (standard) type of data is being used for data input or validation. dataType is an enumeration consisting of all the standard data types in addition to the string (ARRAY OF CHAR) data type.

```
validationProc = PROCEDURE (ADDRESS, dataType): BOOLEAN;
```

Types of validationProc are procedure variables that will be called to test the validity of data input. The procedure variable consists of an address for the data being tested, and the type of data being tested. The procedure variable should return TRUE if the input data passed the test or FALSE if the input data is invalid.

Basic algorithm used for the UserInput Procedure:

```
PROCEDURE UserInput (prompt: ARRAY OF CHAR;
  VAR data: ARRAY OF BYTE;
  length: CARDINAL;
  type: dataType;
  validate: validationProc);
```

A prompt (can be an empty string), a VAR'd data variable, a desired input length, a data type, and a validation procedure variable are passed to the UserInput Procedure.

If the prompt is not an empty string, then it is written to standard output (usually the screen).

A temporary input buffer (string) is used to read character by character from standard input (usually the keyboard) until the enter (return) key is pressed; full editing functions are allowed (home, end, insert, escape, delete, back space, left and right arrow keys).

Only length number of characters are allowed to be entered by the user.

Once the enter (return) key is pressed, the input buffer (string) will be converted to the appropriate data type, and moved into the VAR’d data variable.

Then the validation procedure variable will be called. The NoValidation Procedure (dummy procedure that always returns TRUE) can be called if no validation is necessary. Otherwise a client-module defined procedure is used.

If the data does not pass the validation tests of the validation procedure, then the user must re-enter the data until valid data is entered.

Sample calls:

```
UserInput ("Enter your name: ", name, 25, stringArray, NameCheck);
```

```
UserInput ("Enter your age: ", age, 2, cardinal, NumberCheck);
```

```
UserInput ("Are you married? ", married, 1, boolean, NoValidation);
```

```
UserInput ("Enter your score: ", testScore, 5, real, NumberCheck);
```

A Write should be called after every UserInput, if you want the entries on separate lines.
Sample validation procedures:

PROCEDURE NameCheck (nameAddr: ADDRESS; type: dataType);
VAR
  x, y : CARDINAL;
BEGIN
  IF CHAR (nameAddr^) # CHR (0) THEN
    RETURN TRUE
  ELSE
    ReadCursorPos (x, y);
    GotoXY (25, 20);
    WrStr ("You must enter a name.");
    WrChar (CHR (7));
    GotoXY (x, y);
    RETURN FALSE;
  END;
END NameCheck;

PROCEDURE NumberCheck (numberAddr: ADDRESS; type: dataType);
VAR
  x, y : CARDINAL;
  ok : BOOLEAN;
BEGIN
  CASE type OF
    cardinal : ok := CARDINAL (numberAddr^) > 0
    longcard : ok := LONGCARD (numberAddr^) > 0
    integer : ok := INTEGER (numberAddr^) > 0
    longint : ok := LONGINT (numberAddr^) > 0
    real : ok := REAL (numberAddr^) > 0.0
    longreal : ok := LONCREAL (numberAddr^) > 0.0
  END;
  IF ok THEN
    RETURN TRUE
  ELSE
    ReadCursorPos (x, y);
    GotoXY (25, 20);
    WrStr ("Number must be greater than zero.");
    WChar (CHR (7));
    GotoXY (x, y);
    RETURN FALSE;
  END;
END NumberCheck;

Please feel free to contact me if you have any questions or comments.

Dynamic Strings in Modula-2
by Peter M. Perchansky

Modula-2 and several other high level languages force you to declare the size of arrays prior to compilation time.

This can be very frustrating at times because you usually get caught allocating too much space or too little for the array.

Your program should still work if you allocate too much space, but then you are wasting memory. If you allocate too little space... well we should all know what user's of your program will be swearing ;-) 

Is there an easier/better way?

Well, start thinking of what exactly is an array.

An array is a continuous block of memory going from a lower bound to an upper bounds. The block is usually broken down by segments (elements); each segment accessible by some type of index.

Eg.

```plaintext
stringArray = ARRAY [0..79] OF CHAR;
```

stringArray (depending on the system) takes up one 80-byte block. There are 80 segments (elements) of one byte each. Each segment is accessible by its corresponding (CARDINAL) index (0..79).

What if you were to do your own assigning of memory blocks? What have you created?

A dynamic array. One that only uses whatever memory is necessary to store the elements contained therein.

You might make the following statement in order to create the above array (dynamic style):

```
ALLOCATE (stringArray, 80);
```

to allocate 80 bytes of memory to the variable stringArray. What TYPE would you make stringArray?

You have at least three choices:

```
stringArray = ADDRESS;
stringArray = POINTER TO BYTE;
stringArray = POINTER TO CHAR;
```

I chose to use ADDRESS as my definition of a dynamic string variable since ADDRESS is more portable than BYTE (not all M2 implementations have access to the BYTE data type); while POINTER TO CHAR was a good choice, it is more misleading to the eye since you would think you were pointing only to one CHARACTER.

So you allocated 80 continuous blocks of memory. How do you go about accessing each segment of it?

How about a picture?

<table>
<thead>
<tr>
<th>Peter M. Perchansky</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18</td>
</tr>
</tbody>
</table>

Accessing the first segment is as simple as CHAR (stringArray^); But how would you access the 5th element?

When you allocated your dynamic array, your first character occurs at the base of the ADDRESS. Each character after the first is a given number of bytes from the base.

If you want to access the 5th element, you must advance your address 5 bytes (in the case of CHAR).

TopSpeed Modula-2's library modules come with procedures for Incrementing and decrementing addresses, along with other address manipulation procedures; which is why you will not see my code for such procedures (why reinvent the wheel?).

After you access the elements you want, you must decrement the address back to the base of the array. Otherwise you will lose data or corrupt the memory block (did I state that this was going to be easy?).

How do you know when you have reached the end of a dynamic array? For my purposes, I chose to use the null character (CHR (0)) to denote the end of a dynamic string array.

To make your life easy <grin>, I am publishing my implementation of a module with various procedures for dealing with the creation, assignment, manipulation, and disposal of dynamic strings.

Feel free to make modifications to this module as you see fit; please let me know of your modifications so that I can test them in my programming environment.

Occasionally the need arises to shuffle a list of items. It is a simple task but often the first algorithm that people come up with for the task isn't especially simple or fast. Below are 2 different methods for shuffling that I've come across.

The following discussion uses a deck of cards as an example but the technique can be used for any similar application where you need to shuffle a list of items. The deck is represented as:

```plaintext
aCard = RECORD
  suit : aSuit;
  value : aCardValue;
END;
adeck = ARRAY [ 1..52 ] OF aCard;

PROCEDURE InitDeck( VAR deck : aDeck );
VAR
  s : aSuit;
  v : aCardValue;
BEGIN
  FOR s := clubs TO spades DO
    FOR v := 1 TO 13 DO
      WITH deck[ 13 * ORD(s) + v ] DO
        suit := s;
        value := v;
    END;
  END;
END;
```

To shuffle the deck implies that you rearrange them in place. To deal the deck means that you randomly pick elements out of the deck until they are all gone. If the deck is first shuffled, you can deal the deck by using a for loop to step through the 52 entries in sequence.

**Method 1:**

This method of shuffling calls a random number routine to return a number between 1 and 51. The card chosen by that number is swapped with card number 52. The next card is chosen using a random number call to return a value between 1 and 50 and it is exchanged with the card in location 51. Repeat this until all 52 have been processed. The shuffle code for this method looks like:

```plaintext
PROCEDURE ShuffleDeck( VAR deck : aDeck );
VAR
  i, j : INTEGER;
  t : aCard;
BEGIN
  FOR i := 52 DOWNTO 2 DO
    BEGIN
      t := deck[ i ];
      j := RandomInt( i - 1 );
      deck[ j ] := deck[ i ];
      deck[ i ] := t;
    END;
END;
```

The first algorithm is quite a bit faster. On my machine, it took 1.2 milliseconds to shuffle 52 entries, while the second algorithm took 3.1msecs. These times are only for the ShuffleDeck routines. The second algorithm would probably be faster if a better sort such as QuickSort were used, but it would be even more complicated. So, it looks like the first algorithm scores best on both simplicity and speed.
A Review of Apple's Lisa WorkShop

David Craig
736 Edgewater, Wichita KS 67230
( October 12, 1988 )

INTRODUCTION
The WorkShop was Apple's software development environment for the Lisa during the years 1981 to 1985. From 1981 to 1983 this environment produced all the code for the Lisa. After Apple's Macintosh introduction in 1984 Macintosh developers used the WorkShop since no native Macintosh development environment existed.

The WorkShop is a command line shell similar in appearance to Apple's older Apple // and /// UCSD-like Pascal shells. The main command line provides access to two other command lines, the File Manager and the System Manager, and to several programming tools. The programming tools consist of an editor, Pascal compiler, 68000 assembler, and a linker. Even though the WorkShop supports various languages it is really tailored toward Pascal since most of its utilities are for Pascal source code and object files. The main command line appears as

(V3.9) WORKSHOP: FILE-MGR, SYSTEM-MGR, Edit, Run, Debug, Pascal, Basic, Quit, ?

with the other half of this line being

Assemble, Generate, MakeBackground, Link, TransferProgram

FILE MANAGER
The File Manager provides access to files which are stored either on 400K microdiskettes, hard disks, or tape backup systems. The Lisa Operating System supports a hierarchical file structure which the WorkShop also supports. The command line for the File Manager appears as

FILE-MGR: Backup, Copy, Delete, List, Online, Prefix, Rename, Transfer, Quit, ?

with the other half of this line being

AddCatalog, Equal, FileAttributes, Initialize, Mount, Names, Scavenge, Unmount

With this command line you could backup, copy, and delete files. Wildcard characters within file names are supported for easier file selection. For a directory listing the List command displays a listing complete with file sizes, creation and modification dates, and file attributes. A sample follows:

<table>
<thead>
<tr>
<th>Filename</th>
<th>Size</th>
<th>Psize</th>
<th>Last-Mod-Date</th>
<th>Creation-Date</th>

565 total blocks for files listed
94 blocks of OS overhead for volume and files listed
1115 blocks free out of 17418

The attributes field specifies the attributes of a file. These are defined as follows:

O - File is currently open
C - File was closed by the Operating System
L - File has its Safety flag set (i.e., is locked)
P - File is Protected from copying
S - File was scavenged by the disk Scavenger

The Online command displays a list of the currently mounted devices as follows:

<table>
<thead>
<tr>
<th>DevName</th>
<th>DevAlias</th>

The AddCatalog command creates a new subdirectory, Equal compares files for equality, and Initialize formats disk volumes. The Scavenge command analyses disk volumes for irregularities and repairs them if any problems exist. Mount and Unmount make external devices visible to the Lisa Operating System and the WorkShop. The FileAttributes command produces the following command line:

File Attributes: ClearAttributes, Protect, Safety, AddPassword, RemovePassword, Quit

This command line deletes or specifies new file attributes. The Safety command marks a file as non-deletable so that if you try and delete it the delete will fail. This attribute is very useful for important files. Protect marks a file as protected so that the file can never be copied. This attribute was used by the Lisa Office System (a.k.a. Lisa 7/7) to turn programs into "protected masters". AddPassword and RemovePassword allow file password protection.

SYSTEM MANAGER

The System Manager provides access to several low-level features of the Lisa. Its command line is

SYSTEM-MGR: ManageProcess, OutputRedirect, Preferences, Time, Quit, ?

with the second half appearing as

Console, FilesPrivate, Validate, DefaultPrinter

ManageProcess lists all the current system processes and can terminate executing processes. OutputRedirect redirects all console output to a text file whose name you specify. Preferences runs the Lisa Preferences tool which appears as a window with buttons that are mouse controlled. This window allows you to specify several hardware parameters of the Lisa such as the screen brightness, speaker volume level, and keyboard and mouse sensitivity. Time displays the current clock date and time. Console allows the WorkShop's main console I/O to originate from either the alternate console or an external terminal connected to one of the Lisa's serial ports. FilesPrivate enables the File Manager to have access to special Office System files whose names start with "[".
Generally WorkShop programs should not access these files since their integrity is vital for correct operation of the Lisa Office System.

The Validate command controls several of what are called "paranoia" settings, such as whether file transfers will be verified and whether file selections will require user confirmation for File Manager operations. This allows you to tailor the system to your level of confidence in it and in yourself.

PROGRAMMING TOOLS
The Lisa WorkShop supports several powerful programming tools. Access to these is available through the main command line. The commands in the line for the tools are

   Edit, Debug, Pascal, Basic, Assemble, Generate, Link

The first tool that is usually used is the source code editor. The editor, called LisaEdit, provides full window, menu bar, and mouse support. Menus exist in a menu bar which supports pull-down menus. These handle file creation, opening, saving, and printing. In an early version of LisaEdit the Print menu supported underlining of Pascal keywords. Unfortunately, later versions eliminated this handy feature. Multiple overlapping and resizable windows are available for editing source code files with file size limited only by the amount of memory your Lisa has. With my 1 Mbyte system I have had been able to work with about a dozen large programs. Text resizing is available through the Type Style menu. You can have very small text with about 150 characters per line (cpl) to very large text with about 60 cpl. Cutting and pasting is done with the mouse and the Edit menu which supports the commands Cut, Copy, and Paste. The Lisa's arrow keys on the keypad are supported for cursor movement. The Undo menu command provides the ability to "undo" your last operation. For example, if you Cut some text that was not supposed to be cut Undo will undo the Cut. When you leave LisaEdit and return to the WorkShop main command line the opened windows in LisaEdit remain active. Later, when you reenter LisaEdit the windows appear automatically. This is very handy for modifying a program, leaving LisaEdit to compile the program, and returning to LisaEdit.

The Pascal Compiler is the heart of the Lisa WorkShop. For a detailed review of this compiler's features see my paper titled "A Review of Apple's Lisa Pascal". This compiler generates I-code (intermediate code) which is actually only standard UCSD Pascal P-code. If an error occurs during a compilation the editor is run, the source file is loaded, the cursor is placed over the offending statement, and a specific error message is displayed. The Code Generator, which is run automatically by the Compiler, takes an I-code file and produces 68000 object code. The Linker links different files and libraries to create executable object files. The Compiler and Code Generator display a lot of compilation statistics as the following example shows:

Lisa Pascal Compiler V3.76 (05-Apr-85)  10:50:46 10-Oct-88

That's all Folks!

The Pascal Compiler supports many directives which modify its behavior. For example, you can control integer and sub-range checking, short-circuit boolean evaluation, code optimization control (i.e., off, old scheme, new scheme), program routine name inclusion into the object code for debugging with LisaBug, assembly language listing, and conditional compilation. The last item is implemented using the following directives:

{$DECL var_name} declares var_name to be a conditional variable
{$SETC var_name := expression} sets var_name to a boolean or an integer
{$IFDEF expression} tests if expression is true, if true includes following code
{$IFDEF(expression) the else part in the if-then-else-endif construct
{$ENDIF} the endif part in the if-then-else-endif construct

The assembly listing shows the generated assembly code listed after each source line. The listing for a simple Pascal program follows:

Lisa Pascal Compiler V3.76 (05-Apr-85) 10:51:45 10-Oct-85

1   1 -- PROGRAM RangeTester; {$ASM+}
2   2 -- VAR a : ARRAY [0..9] OF INTEGER;
3   3 --   i : 0..10;
4   4 --
5   5 --

20  10 000026 E340                     ASL.W  #1,D0
21  10 000028 122D 00F8                  MOVE.B  $FFE0(A5),D1
22  10 00002C 4881                    EXT.W  D1
The 68000 Assembler is used to create assembly routines which will later be linked to a Pascal program. Assembly is really used only for time or space critical code.

The Lisa WorkShop supports several other languages which must be purchased separately. A C Compiler was created shortly after the Lisa was introduced, but little programming effort seems to have been done with C due to the Lisa’s overall Pascal perspective. LisaBasic was a rewrite of DEC’s Basic–PLUS language, but since LisaBasic was an interpreter its use never caught on with programmers. LisaCOBOL appeared but was shortly forgotten. One interesting language which Apple developed for the Lisa but was never announced or released was Magic/L (pronounced "magical"). This language was a combination between Pascal and Forth, which I assume Apple Inc. found too exotic even for their revolutionary Lisa.

Debugging Lisa programs is accomplished in either of two ways. The preferred method for Pascal and other high level languages is to write debugging data to the Lisa’s alternate console. This console, whose device name is "-ALTCONSOLE", is displayed when the Right–Option and Keypad–Enter keys are simultaneously pressed. While a program is running it displays debugging data on the alternate console using Pascal’s WRITELN. The program’s execution continues even when this console is displayed. To debug assembler or compiled code LisaBug exists. LisaBug uses the alternate console for both input and output. To debug a program use the Debug command from the main command line and you will be asked for the name of the file to debug. A breakpoint is set at the first instruction of the program and you can then single step, trace, or disassemble the program using various LisaBug commands. Routine names or symbols are available if the compiler’s debugging directive, $D+1$, was enabled. When a runtime error occurs in a WorkShop program LisaBug is invoked. For example, the following Pascal program contains a runtime range error:

```pascal
PROGRAM Range_Tester;

VAR a : ARRAY [0..9] OF INTEGER;
i : 0..10;
```
BEGIN
FOR i := 0 TO 10 DO { <--- Runtime error occurs when i = 10 }
a[i] := i;
END.

When this program runs the Lisa displays the following information on the alternate console and makes this console visible:

Level 7 Interrupt
RANGE_TE+0022 E340 ASL.W #$1,D0
PC=0002002E SR=0000 0 US=00F7FAE6 SS=00C9FE60 DO=1 P#=0008
D0=00000000 D1=00000009 D2=0000FFFF D3=00D00001
D4=00000004 D5=00CC9D54 D6=00F7D80C D7=00CC91E2
A0=A0220E1A A1=00CC91E2 A2=00CE004C A3=00CC9D42
A4=00CC9D42 A5=00F7FC4A A6=00F7FC4A A7=00F7FAE6

CHK RANGE ERROR in process of gid  8
sr = 0 pc = 1311118
saved registers at 13369278
Going to Lisabug, type g to continue

You are now in LisaBug and can issue LisaBug commands. For example, to see the program type "IL RANGE_TE" and the following appears:

>IL RANGE_TE
RANGE_TE+0000 4E56 0000 RANGE_TE LINK A6, #$0000
RANGE_TE+0004 2C5F MOVE.L (A7)+, A6

RANGE_TE+001E 41BC 0009 CHK #$0009,D0
RANGE_TE+0022 E3A0 PC ASL.W #$1, D0
RANGE_TE+0024 122D FFEA MOVE.B $FFE4(A5), D1
RANGE_TE+0028 4681 EXT.W D1
RANGE_TE+002A 3B61 00EC MOVE.W D1, SEC(A5, D0.W)
RANGE_TE+002E 522D FFEA ADDQ.B #$1, FFE4(A5)
RANGE_TE+0032 0C2D 000A FFEA CMPB.B #$000A, $FFE4(A5)
RANGE_TE+0038 6FDE BLE.S $-0200 ; 0020024
RANGE_TE+003A AC22 0290 IUJsr $0220290 ; 00220290
RANGE_TE+003E 4E5D UNLK A5
RANGE_TE+0040 AC22 0220 IUJsr $0220220 ; 00220220
RANGE_TE+0044 4E75 RTS
RANGE_TE+0046 4E5E UNLK A6
RANGE_TE+0048 4E75 RTS

This assembly listing shows in line RANGE_TE+0022 that the program crashed with a range error (CHK RANGE ERROR) since variable i was greater than 9, the last index in array a.
LisaBug can also be invoked at any time by pressing the "-" key on the keypad. This is useful when a program is in an infinite loop situation and nothing will make it stop. Once in LisaBug you can terminate the errant program and return to the WorkShop main command line.

For Macintosh programmers Apple developed the WorkShop Macintosh Software Supplement. This consisted of a set of Lisa diskettes containing Macintosh ToolBox and OS interfaces which allowed total access to every Macintosh feature. Various Macintosh oriented tools for the WorkShop were also provided. This included a resource editor and a resource compiler. For more advanced Macintosh programming Apple released several preliminary versions of MacApp, an object–oriented programming environment centered around the Object Pascal language. MacApp was based upon Apple's work with ToolKit/32, an ambitious object–oriented system based upon Clascal, the predecessor to Object Pascal. ToolKit/32 and Clascal were never supported by Apple since when both of these were near completion Apple diverted its resources toward the Macintosh and away from the Lisa.

EXEC FILES

The program development cycle for a typical application involves a lot of typing. To ease programmers of this burden the WorkShop allows command line input to come from special files, called Exec files. These files are similar to Apple's older /// Pascal Exec facility, but the Lisa version allows Exec files to be created with the editor. The Lisa Exec facility evolved into a very sophisticated Pascal–like language that supports variables, boolean expressions, loops, comments, and file I/O. A simple example follows which compiles two units & a main program, links these items, and runs the final executable file:

```
$EXEC
$
$SET %0 TO 'CARTOG/Map_Util'       { main program file }
$SET %1 TO 'CARTOG/UNewMapMgr'     { new map file manager unit }
$SET %2 TO 'CARTOG/U0ldMapMgr'     { old map file manager unit }
$
P{ascal} %2
{}                                { compile the old map manager unit }
{}                                {}

P{ascal} %1
{}                                { compile the new map manager unit }
{}                                {}

P{ascal} %0
{}                                { compile the main program }
{}
$

L{ink} %0
{}                                { link the main program }
{}                                { link the new map manager unit }
{}                                { link the old map manager unit }
Lisa/UVM                           { link my virtual memory unit }
Lisa/UDebug                        { link my runtime debugger unit }
IO0PasLib                           { link the Lisa Pascal runtime unit }
{}                                {}

}%0                                { send Linker output to the main program }
$
R{un} %0 { run the main program }
$
$ENDEEXEC    { That's all, Folks ... }
LANGUAGE UTILITIES
The WorkShop contains many useful utilities which assist programmers greatly. These utilities 
disassemble compiled programs, edit files at the block level, generate program cross-references, 
etc... The following table summarizes the more important utilities:

<table>
<thead>
<tr>
<th>Utility</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CodeSize</td>
<td>shows the code sizes and names of program segments</td>
</tr>
<tr>
<td>DumpObj</td>
<td>disassembles compiled program code</td>
</tr>
<tr>
<td>DumpPatch</td>
<td>edits files at the block level</td>
</tr>
<tr>
<td>FileDiv</td>
<td>divides large files into smaller files</td>
</tr>
<tr>
<td>FileJoin</td>
<td>joins files divided by FileDiv</td>
</tr>
<tr>
<td>Find</td>
<td>searches text files for strings</td>
</tr>
<tr>
<td>MacCom</td>
<td>transfers files to and from Lisa and Macintosh microdiskettes</td>
</tr>
<tr>
<td>PasMat</td>
<td>formats Pascal source files using many options</td>
</tr>
<tr>
<td>ProcNames</td>
<td>shows the names and lexical levels of Pascal program routines</td>
</tr>
<tr>
<td>RMaker</td>
<td>compiles a resource file for Macintosh programs</td>
</tr>
<tr>
<td>SegMap</td>
<td>shows the code segments in a program</td>
</tr>
<tr>
<td>ShowInterface</td>
<td>shows the interface portion of a Pascal Unit object file</td>
</tr>
<tr>
<td>UXRef</td>
<td>shows the routine relationships in a compiled program</td>
</tr>
<tr>
<td>XRef</td>
<td>shows the variable/routine cross-references in a source file</td>
</tr>
</tbody>
</table>

Two other features make the WorkShop well rounded. The TransferProgram command in the 
main command line runs a mouse- and window-based telecommunication's program. This is ideal 
for accessing a programming BBS and downloading source code. The MakeBackground command 
allows programs to be run as a background process. With this feature you can run several programs 
at once, but with several programs running concurrently system performance can become degraded.

CONCLUSION
For the past decade I have worked with many different computers, from programmable hand-held 
calculators to mainframes and from 1984 onward I have used a Lisa for programming mainly in 
Pascal. Overall, I have found the Lisa WorkShop to be a very powerful development system for 
creating, compiling, and debugging large programs. Even when compared to the other machines that 
I have worked with the Lisa WorkShop still comes out as being both a professional and powerful 
development environment.

<<< That's all, Folks ... >>>
WDS Extract Program
by William D. Smith

This program is used to extract words from Pascal source files. The words are written to a file for later processing (more on this next time). To use, enter names for the "input file," the "output file" (which defaults to "E.<input file>" after entering the input file) and the "skip words file" (which is optional). Any words in the "skip words file" are skipped when the input file is read. (My default "skip words file" has a list of all Pascal keywords and reserved words. This produces a list of all the words declared or used in the source file.) Words within comments and quotes are ignored.

The figure at the bottom of the page shows what you see as the program is running. "I!" redisplays the screen, "E(xtract)" extracts the words, "E(X)amine" lets you examine the files and "Q uit" exits the program. "I", "O" and "S" let you change the file names. The at symbol "(@)" on the "input file" and "skip words file" lines allows you to enter the name of a file containing a list of file names which are processed instead of the named file by prefixing the file name with the at symbol.

The output file, shown on the next page, contains comment lines identifying the program, the date and time which files are used and how. Then the number of words output (used in processing the file later) and finally the list of words, in alphabetical order, one per line.

The data structures used in the program are fairly simple. Entries is an array of records with two fields, Skip to tell if the word should be printed, which is set to true when words are read from the "skip words file(s)" and set to false when the words are read from the "input file(s)." The second field is an index into the Strs array (more on this later).

The grunt work in this program is done in the function NextWord which parses each line and returns one word at a time. When the end of a line is reached, NextWord gets the next line of the file. The function Ins_Str (called in the while loop of Readfile) finds or inserts the word into the Strs array and returns the index of the word. No duplicates are inserted in the array.

The Entries array is then sorted alphabetically, ignoring case and underlines, and then printed. The quick sort routine described in the February 1989 NewsLetter is used for the sorting. The greater than or equal function, Geq, controls the sort order.

Now for some tricky stuff. The include file "I.INS_STR.TEX" contains the Ins_Str function. A long time ago, I wrote an application (which is still in use) which needed to have in memory many names. Each name was stored on disk as string [23] as part of a complex record structure. I didn't have enough space to put all the names in memory at the same time. Statistics on the names showed that the shortest name was 2 characters, the longest was 22 and the average was 11. 23 characters take up 12 words of memory while 11 characters take up only 6 words. There were also many duplicates (about 15 percent). Thus by removing duplicates and using an average of 6 words, I could get them all in memory. So what I needed was a data structure which was very space efficient in terms of storing strings.

Extract: ! <options> E(xtract) eX(amine) Q uit
Words: 137, Size: 480

I = Input file (@) -------> EXTRACT.TEX
O = Output file ---------> E. EXTRACT.TEX
S = Skip words file (@) ----> M22.WORDS.PAS.TEX

Extracting from EXTRACT.TEX
< 100>............

(c) Copyright 1987 to 1990 by William D. Smith, All rights reserved
Knowing something about how the compiler and strings interacted, I devised the following scheme: any program which needed to store variable length strings in memory would declare an array of string [ ]. This indicates that each word in the array is a string of length one. (The first byte of a string is the length and strings always use an even number of bytes of storage although the last byte may not be used.) Ins_str returns the index of string in the array. To do this, it searches through the array and finds the string in which case the index is returned, or does not find it, in which case the string is inserted and the index where the string was inserted is returned. Any index not returned by Ins_str is not allowed (eg. 2 in the following example) because a legal string does not start at that point. The array is used by naming it with an index (eg. Strs [Nm] in P_Entries). This technique works because all strings are type compatible. By convention the first string in the array is always the empty string.
In the following example, **Ins_Str** returns 3 when called with "for" and returns 5 when called with "to". The string "to" is inserted into the array at index 5. 2, 4 & 6 are illegal indices. "A"s are unused bytes. The index is by words.

<table>
<thead>
<tr>
<th>index</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>before:</td>
<td>[</td>
<td>^</td>
<td>2</td>
<td>d</td>
<td>0</td>
<td>o</td>
<td>3</td>
</tr>
<tr>
<td>after:</td>
<td>[</td>
<td>^</td>
<td>2</td>
<td>d</td>
<td>0</td>
<td>o</td>
<td>3</td>
</tr>
</tbody>
</table>

**Ins_Str** uses a modified Boyer-Moore search. The first word of the string to be inserted (the length byte and the first character) are compared to the first string. If they don't match, the index into the array is incremented by the length of the string. If they match, the string is then compared to the string in the array at the index location. Again, if they don't match the string is incremented by the length of the string in the array. This is repeated until a match is found or the unused part is found. New strings are always inserted at the end. For reasons of speed, part of **Ins_Str** is coded using the pmachine instruction.

System: Power System version IV.2.2
Compiler: Power System Pascal Compiler
Keywords: WDS Extract Program Pascal

Description: This program extracts all the words from the input file.
  Lines begining with a period in the "skip words file" are
  ignored. Words in comments and quotes are skipped in the
  "extract from file". It then prints out all those words
  which are not in the "skip words file".

Change log: (most recent first)

The conditional compiler directives "BYTE" and "INS_STR_FWD" are declared in the include file "VERSION_TEXT". "BYTE" is true for byte addressed machines and false for word addressed machines. "INS_STR_FWD" is redeclared in the program including the file if Ins_Str must be declared forward. This include file should actually be turned into a unit, but I haven't had time to do that. I've used it successfully in 15 to 20 different programs on several different machines and versions of the p-System. I stripped out some code for different machine versions to save space.

Insert a str in an array of strs [1.00] --- 23 Oct 87 | \{|xjm$dlinx|f8|e1. \} |

System: Power System version IV.2.2
Compiler: Power System Pascal Compiler
Keywords: WDS Insert String Include
Description: Insert string include file. This file contains a function
             for inserting strings in an array of Str_1. If there is no more
             room to add a name into the array A, Ins_Str is returned as
             MinStr and N (the index of the next unused string in the array)
             is set to Null. Prior to use, N must be set to MinStr + 1
             and the first word of A must be filled with Nuls (0). S is the
             string to be inserted and is unchanged.

Board Meeting Minutes (April 11, 1990)
By Keith R. Frederick

Minutes of the Board Meeting of USUS, Inc, held in room 1 of the MUSUS forum teleconferencing facility on the CompuServe Information Service April 11, 1990.

Present at the meeting were:

User ID Name
74076,1715 Felix Bearden (Felix) with Bob Spitzer (BobS) BoD
76702,513 Harry Baya (Harry)
73447,2754 Henry Baumgarten (Henry) BoD
72767,622 Tom Cattrall (TomC) BoD
73760,3521 Keith Frederick (Keith)
72747,3126 Bob Clark (BobC)

Topics dealt with were (primarily based on a proposal by Hays):

TRADING THE SAGE IV

The first item on the agenda was a proposal by Hays suggesting that USUS trade the Sage IV for peripherals that would be used on the Sage II, which was deemed adequate for the administrative duties that would be delegated to it. Since Felix Bearden is the new administrator, Henry, Tom, and Harry echoed that if Felix didn’t mind they would vote for the trade. Felix mentioned that it didn’t directly affect him since he would use his 460 anyway, but that future administrators would need the peripherals. So, the motion to trade the Save IV for peripherals for the Sage II was voted upon and unanimously approved. Felix stated he would implement the motion.

ADVERTISING IN JPAM

Felix suggested that as soon as the JPAM agreement was implemented USUS should place an ad in JPAM. The price would be about $1100 for a one-third page ad.

Bob Clark, Treasurer, noted the ad price is about one-fifth of the current bank balance of USUS and stated the account is slowly draining away. Tom Cattrall felt the advertisement is too much considering the present state of USUS and suggested looking for lower cost alternatives or just waiting. Bob Spitzer suggested that since USUS has a bad case of the dwindles sitting tight won’t do anything to help and we need to invest in a shot of growth. Also pointing out that given JPAM’s circulation of over 15,000, even a tiny response would be dramatic.

Bringing up a related topic, Bob Clark asked about the plan to have a USUS column in JPAM. Bob Spitzer commented that the column issue is up in the air and getting an author is an important limiting factor. Tom Cattrall suggested that the idea of an article in JPAM coupled with upcoming MUSUS publicity would be better considering the resources of USUS at the moment. Further stating that our best bet would be to start with an article or two in JPAM that got USUS in the public eye.

However, Bob Spitzer, reminded everyone that if an article was submitted this summer it would not get reviewed, revised, and published until a year from the submission. Having a regular column would be just as bad and that the advertisement would be needed to tell everyone about USUS. Also, it would only take twenty new trial memberships to pay back the $1100.

Henry stated that his calculation is a bit more conservative, estimating forty or fifty new memberships would be needed to pay for the advertisement. Tom Cattrall commented that even Henry’s number is not enough given USUS also gives new members many benefits that cost money. Tom also stated that the JPAM editorial cycle is currently quite fast, although some delay would still occur.

Bob Clark asked if we got any benefit from joining with JPAM. Felix answered stating that our affiliation will build with JPAM, but for now at least USUS can say join us and you get JPAM as part of the package. Felix then asked if anyone had ideas on letting the world know about USUS. Tom restated his wish to look at alternatives to the $1100 advertisement and suggested that we discuss this on MUSUS in the coming days.

Bob Spitzer replied that his experience in the computer world showed that if you don’t advertise, you aren’t seen. Tom responded that USUS should at least consider all options before deciding on the solution.

Henry proposed a compromise; prepare an ad and we can decide whether or not it would be likely to have the desired affects. Henry also indicated that he tends to favor the ad. Felix and Bob Spitzer said they would give the writing of the text for the advertisement a try and Harry mentioned he would like to take a shot at the artwork.

BOARD MEMBER PARTICIPATION

A proposal was made to try and remove board members who don’t participate in the meetings. Since the current bylaws don’t provide for such an action, Felix stated that we would write a motion to revise the bylaws at the next meeting. Tom Cattrall suggested that non-participating board members, indicating Frank Lawyer and Stephen Pickett as such, be asked to participate or resign. Also noting that he would rather have them show up than resign.

Felix suggested that a change in the bylaws would be the least painful way of taking care of the situation. Harry thought
though, that the problem is not too great in that if a board member was asked to resign he probably would. Also, Harry stated that he has talked to Frank Lawyer recently and Frank was very busy and would probably accept a request to attend or resign.

Henry mentioned that Frank should be given a chance to decide but Stephen Pickett asked for the task and has only showed up for one meeting. Henry said he should be reminded or removed. However, Tom Catrall realized that since Stephen Pickett had not been on MUSUS in some time he might not know he was elected. No one notified him and the newsletter, which mentions the election result, hadn't been mailed yet.

The topic of what to do was tabled until the next meeting.

[Minute Taker’s Note: Tom Catrall was correct; Stephen Pickett was not notified of his victory in the election and did not know he was elected.]

APPLE II STUFF

Hays had mentioned that he would safeguard the Apple IIe and master copies of the software library until USUS decides on what to do with it. Harry indicated that Frank Lawyer, current leader of the Apple II SIG, should be asked if we want the Apple //e and if he would attend future board meetings.

Keith Frederick indicated that if the Apple II section needed someone to support it, he would volunteer. Henry mentioned that Frank has done an excellent job in the past and would be asked first he wants to continue heading the Apple II SIG.

NEXT MEETING

The Board agreed to adjourn and meet again at 6:30 PM PST / 7:30 MST / 8:30 CST / 9:30 EST May 9th 1990 in Room 1 of the MUSUS conference facility.

From The Editor
by Tom Catrall

This is probably the biggest issue yet of the USUS newsletter. The backlog of articles is just about gone now. So, if you have an idea for an article, a review, or a letter, now is the time to send it in. Short items are especially welcome. With only long articles, it is difficult to make the size come out to the proper number of pages.

Sanyo PC Hackers Newsletter

In the last issue I forgot to mention that the inspiration for the review of the Impact print head repair service came from the Sanyo PC Hackers Newsletter. They had some discussions of trying to find replacement print heads and it occurred to me that I should write up my experiences. When the article came out, Victor Frank, the editor of the newsletter, called me to ask permission to reprint the article.

He included a word about USUS in the introduction and I feel it only fair that I mention his group as well. It covers the orphaned Sanyo 16 bit computers and provides a newsletter and a large (over 250 volumes) disk library. It looks like a good resource for anyone with a Sanyo computer.

Victor R. Frank
12450 Skyline Blvd.
Woodside, CA
94062-4541

Dues: $20/yr US, C$25 Canada, $25 surface mail elsewhere, $35 foreign airmail

Victor also mentioned that he has a Stride but hasn’t done much with it yet. He said that some beginner’s level articles on the Stride and the P-system would interest him. Is there anyone out there that has recently gone through the learning curve? If so, how about writing up some of your observations?

USUS board meeting minutes

There has been some discussion on MUSUS about how to report the board meeting minutes in the USUS newsletter. My position has been that people don’t join USUS to read meeting minutes, and therefore I advocate a "minimalist" approach. Provide just enough to give people an idea of what is going on but don’t get into lots of detail.

The danger in this is that some positions may not be adequately represented. An example is in this issue’s minutes. During the discussion of board members that weren’t attending meetings, I said that having only 3 board members out of 5 as regular participants made getting a quorum difficult. So I suggested that either the 2 missing members start attending or resign so that we would only need 50% of 3 rather than 50% of 5 in order to conduct business. In the minutes, my discussion of the quorum difficulties was not included. Thus, the reasons why we discussed "getting rid of" board members might be misinterpreted.

In spite of these possible misunderstandings, I still feel that small is better regarding minutes. But, I figured I’d bring it up in case anyone would like to lobby for another policy. If there is any meeting for which you wish to have more detail, contact me or another of the attendees and we could provide you with a complete transcript.

Submission Guidelines

Submit articles to me at the address shown on the back cover. Electronic mail is probably best, disks next best, and paper copy is last. If your article has figures or diagrams, I can use encapsulated Postscript files in any of the disk formats listed below. If you can’t produce encapsulated Postscript, then paper copy is probably the only practical method for submitting graphics.

You can send E-Mail to my Compuserve ID: 72767,622, or indirectly from internet: 72767,622@compuserve.com. For disks, I can read Sage/Stride/Pinnacle format disks. Also, any MS-DOS 3.25 or 3.5 disks, and 3.5" Amiga disks. If anyone wants to send Mac format disks I could probably get someone to translate them into something I can use. Whatever you send, please mark on the disk what format it is. That will save me a lot of guesswork.

Text should be plain ascii rather than a word processor file. It can have carriage returns at the end of all lines or only at the ends of paragraphs. What you send doesn’t have to look pretty. I will take care of that. My spelling checker will take care of spelling errors too. If you want special formatting use the following conventions:

1. _Underline_, put an underline character at each end of the section to underline.
2. *Bold*, put a star at each end of the section to bold.
3. *Italics*, put a caret at each end of the section to be set in italics.
4. ??Special requests??, such as ??box next paragraph?? should be surrounded with "?? ??".
